

UK Patent Application - Abstract

ABSTRACT

A computer-implemented system enables users to predict and optimise interpersonal communication outcomes through multi-dimensional strategic variable modelling, probabilistic simulation, and closed-loop accuracy calibration. The system quantifies communication characteristics across five ontological layers, executes Monte Carlo simulations incorporating user-configurable confounding factors and strategy adjustments to generate probabilistic outcome predictions across three strategic dimensions (Notoriety, Respect, Financial Wealth), records empirical post-interaction observations, and calculates prediction accuracy metrics to refine future estimations. Novel technical contributions include a cognitive distortion logging system integrated with communication planning, a seven-dimensional strategic effectiveness measurement framework, a five-factor confounder penalty algorithm affecting skill performance, and a project management architecture specifically designed for communication objectives rather than generic deliverables. The system provides measurable technical advantages in sales optimisation, negotiation preparation, stakeholder management, and strategic relationship development by enabling systematic strategy testing and continuous prediction improvement through empirical validation.
